Facts of live

The big picture @ 8TeV

- Peak at Z mass due to singly resonant diagrams.
- Interference is an important effect.
- Destructive at large mass, as expected.
- With the standard model width, \mathcal{B}_H , challenging to see enhancement/deficit due to Higgs channel.

Direct Higgs width measurement

- N.B.: see earlier talk in this session for indirect width measurement.
- Analytical m_H (non-relativistic Breit-Wigner) model convoluted with detector resolution with width Γ_H (m_H and μ free parameters) ($\Gamma_H = 4 \text{ MeV}$ at 125 GeV)
- Analysis assumes no interference with background processes
- $H \rightarrow ZZ^* \rightarrow 4l$:
 - Event-by-event modelling of detector resolution
 - Per-lepton resolution functions use sums of 2(3) Gaussians for muons (electrons)
 - Validated by fitting mass peak for $Z \rightarrow 4l$ using convolution of detector response with BW for Z mass
 - 95% CL: $\Gamma_H < 2.6 \text{ GeV}$ (exp. limit 3.5 GeV for $\mu = 1.7, 6.2 \text{ GeV}$ for $\mu = 1$)
- $H \rightarrow \gamma\gamma$:
 - 95% CL: $\Gamma_H < 5.0 \text{ GeV}$ (expected limit 6.2 GeV for $\mu = 1$)

OFF – SHELL I

When a particle physicist describes something as "off mass-shell", they could be referring to a precise bit of quantum mechanics, or denouncing an unrealistic budget estimate, J. Butterworth

We define an **off-shell production cross-section** (for all channels) as follows:

$$\sigma_{ij \rightarrow \text{all}}^{\text{prop}} = \frac{1}{\pi} \sigma_{ij \rightarrow \text{H}} \frac{s^2}{|s - s_{\text{H}}|^2} \frac{\Gamma_{\text{H}}^{\text{tot}}}{\sqrt{s}}$$

☞ When the cross-section $ij \rightarrow \text{H}$ refers to an off-shell Higgs boson the choice of the QCD scales should be made according to the virtuality and not to a fixed value. Therefore, for the PDFs and $\sigma_{ij \rightarrow \text{H}+\text{X}}$ one should select $\mu_{\text{F}}^2 = \mu_{\text{R}}^2 = z s/4$ ($z s$ being the invariant mass of the detectable final state).

OFF – SHELL II

If you come out of your shell, you become more interested in other people and more willing to talk and take part in social activities
Cambridge Dictionaries

Let us consider the case of a *light Higgs boson*; here, the common belief was that

☞ the product of **on-shell production cross-section** (say in gluon-gluon fusion) and **branching ratios** reproduces the correct result to great accuracy. The expectation is based on the well-known result ($\Gamma_H \ll M_H$)

$$\Delta_H = \frac{1}{(s - M_H^2)^2 + \Gamma_H^2 M_H^2} = \frac{\text{ON}}{M_H \Gamma_H} \delta(s - M_H^2) + \text{PV} \left[\frac{\text{OFF}}{(s - M_H^2)^2} \right]$$

where **PV** denotes the principal value (understood as a distribution). Furthermore s is the Higgs virtuality and M_H and Γ_H should be understood as $M_H = \mu_H$ and $\Gamma_H = \gamma_H$ and not as the corresponding on-shell values. In more simple terms,

- ☞ the first term puts you on-shell and the second one gives you the off-shell tail
- ☞ Δ_H is the Higgs propagator, there is no space for anything else in QFT (e.g. Breit-Wigner distributions).

Consider only the case of a light Higgs boson, i.e. it covers k^0 for $M_H \ll \sqrt{s}$.

⚡ The product of an off-shell production cross-section (to be given later) and branching ratio approximates the overall cross-section. The approximation is valid for the off-shell region $\sqrt{s} \gg M_H$.

$$\Delta_{ii} = \frac{1}{(s - M_H^2)^2 + \Gamma_H^2 M_H^2} = \frac{\pi}{M_H \Gamma_H} \delta(s - M_H^2) + \text{PV} \left[\frac{1}{(s - M_H^2)^2} \right]$$

where PV denotes the principal value distribution and δ is the Dirac delta function. For $M_H \ll \sqrt{s}$, the second term is negligible and the first term dominates. For $M_H \sim \sqrt{s}$, the second term is important and the first term is suppressed.

⚡ The first term puts you on-shell and the second one gives you the off-shell tail.

⚡ M_H is the Higgs propagator, there is no space for anything else in $\mathcal{O}(T)$ (e.g. Breit-Wigner distributions).

We define an off-shell production cross-section (for all channels) as follows:

$$\sigma_{\text{off-shell}}^{\text{prod}} = \frac{1}{s} \sigma_{\text{off-shell}} = \frac{\sigma^2}{|s - M_H^2|^2} \frac{\Gamma_H^2}{\sqrt{s}}$$

⚡ When the cross-section $\sigma \rightarrow \text{BR}$ refers to an off-shell Higgs boson the choice of the QCD scales should be made according to the virtuality and not to a fixed value. Therefore, for the PDFs and $\sigma_{\text{off-shell}}$ one should select $\mu_F^2 = \mu_R^2 = 2s/4$ ($2s$ being the invariant mass of the detectable final state).

OFF – SHELL III

A short History of beyond ZWA (don't try fixing something that is already broken in the first place)

- ① There is an enhanced Higgs tail Kauer - Passarino (arXiv:1206.4803): away from the narrow peak the propagator and the off-shell H width behave like

$$\Delta_H \approx \frac{1}{(M_{VV}^2 - \mu_H^2)^2}, \quad \frac{\Gamma_{H \rightarrow VV}(M_{VV})}{M_{VV}} \sim G_F M_{VV}^2$$

- ② Introduce the notion of ∞ -**degenerate** solutions for the Higgs couplings to SM particles Dixon - Li (arXiv:1305.3854), Caola -

Melnikov(arXiv:1307.4935)

- ③ Observe that the enhanced tail is obviously γ_H -independent and that this could be exploited to constrain the Higgs width model-independently
- ④ Use a matrix element method (MEM) to construct a kinematic discriminant to sharpen the constraint

Campbell, Ellis and Williams (arXiv:1311.3589)

$\Delta\Gamma$ & $n\Gamma$ or $n\gamma$ beyond Z WA (start by being something that is already broken in the first place)

- ① There is an enhanced Higgs tail source: Peskin & Schroeder (1997, 2002): away from the narrow peak the propagator and the off-shell W width behave like

$$\Delta\Gamma \sim \frac{1}{(M_{H^\pm}^2 - \mu_{H^\pm}^2)}, \quad \frac{\Gamma_{H^\pm \rightarrow \nu\bar{\nu}}(M_{H^\pm})}{M_{H^\pm}} \sim G_F M_{H^\pm}^2$$

- ② Introduce the notion of **degenerate** solutions for the Higgs couplings to $1N$ particles source: LQ (96-100, 1996), Gaiotto & Marcolli (2017, 2019)
- ③ Observe that the enhanced tail is effectively independent and that this could be exploited to constrain the Higgs width rather independently
- ④ Use a multi-statement method (e.g. χ^2) to construct a likelihood discriminant to separate the scenarios Demiguel, Ellis and Williams (arXiv:1211.2695)

OFF – SHELL IV

Off-shellness forever

arXiv:1308.0422

Crucial for the case of a light Higgs boson: the narrow width approximation

• The notion of an off-shell production cross-section (in green color below) and branching ratios (represented in the second case by green arrows). The approximation is based on the narrow width approximation $\Gamma_H \ll M_H$.

$$\sigma_{\text{off-shell}} = \frac{1}{(s - M_H^2)^2 + \Gamma_H^2 M_H^2} \times \text{PV} \left[\frac{1}{(s - M_H^2)^2} \right]$$

where PV denotes the principal value (understood as a distribution). Furthermore by the Higgs unitarity and $M_H^2 \ll s$ should be understood as $M_H^2 \ll s \ll \Lambda^2$ with Λ not as the corresponding cut-off value, but as the UV-cutoff.

• The first term puts you on-shell and the second one gives you the off-shell tail

• $\sigma_{\text{off-shell}}$ is the Higgs propagator, there is no space for anything else in QFT (e.g. Breit-Wigner distributions).

off-shell production cross-section (for all channels) as follows:

$$\sigma_{\text{off-shell}}^{\text{prod}} = \frac{1}{s} \sigma_{\text{prod}} \times \frac{\Gamma_H^2}{(s - M_H^2)^2 + \Gamma_H^2}$$

• When the cross-section $\sigma \rightarrow H$ refers to an off-shell Higgs boson the choice of the QCD scales should be made according to the virtuality and not to a fixed value. Therefore, for the PDFs and $\sigma_{\text{prod}} \rightarrow H$ one should select $\mu^2 = \mu_0^2 = \frac{2s}{4}$ ($2s$ being the invariant mass of the detectable final state).

A summary of beyond ZWA (start by being something that is already known in the first case)

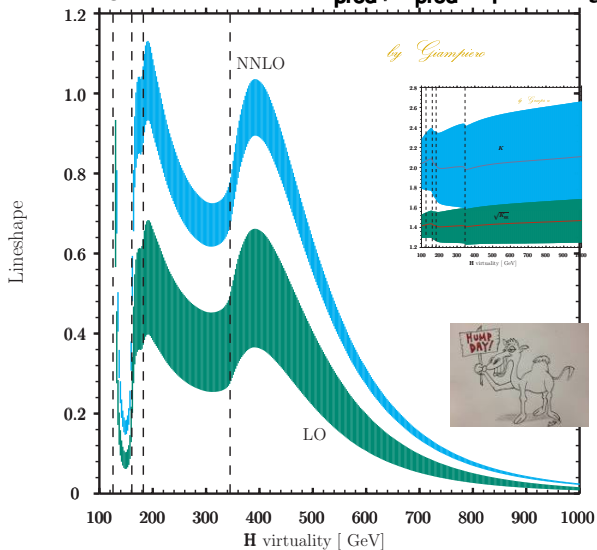

- There is an enhanced Higgs tail (from $\sigma_{\text{prod}} \rightarrow H$), away from the narrow peak the propagator and the off-shell H width behave like

$$\sigma_{\text{off-shell}} \sim \frac{1}{(M_H^2 - \mu^2)^2} \times \frac{\Gamma_H - \gamma_V(M_H)}{M_H \gamma_V} \sim G_H M_H^2 \gamma_V$$
- Introduce the notion of **degenerate solutions** for the Higgs couplings to γ_V particles (from $\sigma_{\text{prod}} \rightarrow H$).
- Check if the enhanced tail is obviously γ_V independent and that this would be equivalent to constant Higgs width model independence.
- Use a matrix element method (MxM) to construct a likelihood distribution to bypass the constant $\sigma_{\text{prod}} \rightarrow H$ (from $\sigma_{\text{prod}} \rightarrow H$).

Compt. Riv. and Wilton (arXiv:1311.2888)

MHOU(THU)

The higher-order correction in gluon-gluon fusion have shown a huge **K-factor** $K = \sigma_{\text{prod}}^{\text{NNLO}} / \sigma_{\text{prod}}^{\text{LO}}$, $\sigma_{\text{prod}} = \sigma_{\text{gg} \rightarrow \text{H}}$.

Futher details

The ratio is K_{gg}/K with quadratically subtracted uncertainties of K from the uncertainty of K_{gg}

Assumption: the extra HO terms calculated in K give an uncorrelated extra MHO uncertainty of 20–30% which needs to be applied to K_{gg} on top of the correlated K MHO

Courtesy of M. Duehrssen

subleading systematics on I or B alone are important as the leading systematics on I+B could cancel to some degree. Because of the negative I, 100% correlating is actually not conservative as this allows larger cancellations in S + I

1 The zero-knowledge scenario

The *soft-knowledge* scenario: in a nutshell, one can

$$\begin{aligned}\sigma &= \sigma^{\text{LO}} + \sigma^{\text{LO}} \frac{\alpha_s}{2\pi} [\text{universal} + \text{process dependent} + \text{reg}] \\ &\rightsquigarrow \kappa(M_{ZZ}) \mathbf{S} + \kappa_{\text{gg}}(M_{ZZ}) \left[\sqrt{\lambda} \mathbf{I} + \lambda \mathbf{B} \right]\end{aligned}$$

- ☛ where *universal* (the “+” distribution) gives the bulk of the result
- ☛ while *process dependent* (the δ function) is known up to two loops for \mathbf{S} but not for \mathbf{B}
- ☛ and *reg* is the regular part.

A possible strategy ([arXiv:1304.3053](https://arxiv.org/abs/1304.3053)) would be to use for \mathbf{B} the same *process dependent* coefficients and allow for their variation within some ad hoc factor, e.g. $\lambda \in [1/2, 2]$.

WW ? EXP: something like the p_T distribution is not part of the LO calculation at all.

TH: something is moving

Questions

dialogue concerning the two chief world systems

Question about the deficit expected/observed (ATLAS + CMS):
should we start worrying about TH drivenness of the deficit?

- ☛ The ATLAS off-shell measurement is basically spot on with the SM. Compared to that, CMS has a larger deficit in the off-shell high mass region.
- ☛ Then, when combining with the on-shell measurement, ATLAS develops a deficit because on-shell μ for ZZ is ≈ 1.5 . On the other hand, for CMS the on-shell is ≈ 0.9 , so it actually goes back in the other direction.

W In the end this does not allow to draw any physics conclusion

Nevertheless what is observed (expected) and what are the assumptions?

Definitions and assumptions

☞ the kosher *experimental* answer

- ✓ EXPECTED \mapsto generate Asimov dataset with $\mu_{\text{VBF}} = \mu_{\text{ggH}} = 1$, fit with floating μ_{VBF} and μ_{ggH}
- ✓ OBSERVED \mapsto float μ_{VBF} and μ_{ggH}

☞ the poor *theoretical* understanding

- ✓ EXPECTED is what you get from a MC with $\mu = \mu_{\text{hyp}}$
- ✓ OBSERVED is what you get by fitting the data

Although I understand *questions* and *comments*

- ✓ What is wrong in plotting what you expect to the likelihood to look like when everything else is as expected in the SM?
- ✓ The post-fit expectation is a very important concept

Making on-shell hypothesis ($\mu_{\text{OS}} = 1$ or $\mu_{\text{OS}} = \mu_{\text{obs}}$) is a consequence of assuming on-shell ∞ -degeneracy, which is not realistic. Which BSM theory allows you to *fix* the on-shell and to *float* the off-shell?

Logic takes care of itself; all we have to do is to look and see how it does it

K language

$$\sigma_{i \rightarrow H \rightarrow f} = (\sigma \cdot \text{BR}) = \frac{\sigma_i^{\text{prod}} \Gamma_f}{\gamma_H}$$

$$\sigma_{i \rightarrow H \rightarrow f} \propto \frac{g_i^2 g_f^2}{\gamma_H}$$

$$g_{i,f} = \xi g_{i,f}^{\text{SM}} \quad \gamma_H = \xi^4 \gamma_H^{\text{SM}}$$

a consistent BSM interpretation?

On the whole, we have a constraint in the multidimensional κ -space

$$\kappa_g^2 = \kappa_g^2(\kappa_t, \kappa_b) \quad \kappa_H^2 = \kappa_H^2(\kappa_j, \forall j)$$

On-shell ∞ -degeneracy
arXiv:1305.3854, 1307.4935, 1311.3589

The generalization is an ∞^2 -degeneracy
 $g_i^2 g_f^2 = \gamma_H$

$g_i \leftrightarrow \kappa_j$
 $g_i(M_H) ? g_i(\sqrt{s})$

Simplified version

$$\frac{\Gamma_{gg}}{\Gamma_{gg}^{\text{SM}}(\mu_H)} = \frac{\kappa_t^2 \cdot \Gamma_{gg}^{tt}(\mu_H) + \kappa_b^2 \cdot \Gamma_{gg}^{bb}(\mu_H) + \kappa_t \kappa_b \cdot \Gamma_{gg}^{tb}(\mu_H)}{\Gamma_{gg}^{tt}(\mu_H) + \Gamma_{gg}^{bb}(\mu_H) + \Gamma_{gg}^{tb}(\mu_H)}$$

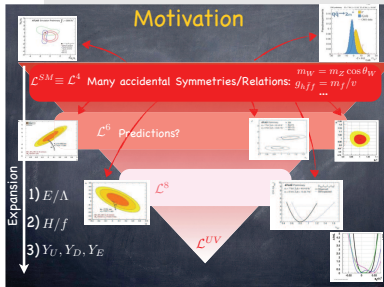

original κ -language arXiv:1209.0040

Only on the assumption of degeneracy one can prove that off-shell effects measure γ_H

a combination of on-shell effects measuring $g_i^2 g_f^2 / \gamma_H$
and off-shell effects measuring $g_i^2 g_f^2$
gives information on γ_H
without prejudices

\curvearrowright N defines LO

PTG: T - generated in at least one extension of SM

PROPOSITION: There are two ways of formulating HEFT

- a) mass-dependent scheme(s) or **Wilsonian** HEFT
- b) mass-independent scheme(s) or **Continuum** HEFT (CHEFT)
 - only **a)** is conceptually consistent with the image of an EFT as a low-energy approximation to a high-energy theory
 - however, inclusion of NLO corrections is only meaningful in **b)** since we cannot regularize with a cutoff and NLO requires regularization
 - There is an additional problem, CHEFT requires evolving our theory to lower scales until we get below the "heavy-mass" scale where we use $\mathcal{L} = \mathcal{L}_{\text{SM}} + \mathbf{d}\mathcal{L}$, $\mathbf{d}\mathcal{L}$ encoding matching corrections at the boundary. Therefore, CHEFT does not integrate out heavy degrees of freedom but removes them compensating for by an appropriate matching calculation

☞ *Not quite the same as it is usually discussed (no theory approaching the boundary from above ...)* cf. low-energy SM, weak effects on $\mathbf{g}-2$ etc.

Footnotes
Annotations

$\dim \phi = d/2 - 1$

$\dim \mathcal{O}^d = N_\phi \dim \phi + N_{\text{der}}$

For $d \geq 3$ there is a finite number of relevant + marginal operators

For $d \geq 1$ there is a finite number of irrelevant operators

Sounds good for finite dependence on high-energy theory

This assumes that high-energy theory is weakly coupled

Dimensional arguments work for LO HEFT

In NLO HEFT scaling may break down, implying
appeal to a particular renormalization scheme

Ren. group should only be applied to EFTs that are nearly massless

Decoupling theorem fails for CHEFT, but, arguably this does not prevent them from supporting a well defined scheme, but decoupling must be inserted in the form of matching calculations (which we don't have ...)

Match Feynman diagrams \in HEFT with corresponding **1**(light)**PI** diagrams \in high-energy theory
(and discover that Taylor-expanding is not always a good idea)

What do we lose without matching?

Melius abundare quam deficere

Figure 4: The general form of a matching calculation.

terms.

In this region, the physics is described by a set fields, χ , describing the heaviest particles, of mass M , and a set of light particle fields, ϕ , describing all the lighter particles. The Lagrangian has the form

$$\mathcal{L}_M(\chi, \phi) + \mathcal{L}(\phi), \quad (3.15)$$

where $\mathcal{L}(\phi)$ contains all the terms that depend only on the light fields, and $\mathcal{L}_M(\chi, \phi)$ is everything else. You then evolve the theory down to lower scales. As long as no particle masses are encountered, this evolution is described by the renormalization group. However, when μ goes below the mass, M , of the heavy particles, you should change the effective theory to a new theory without the heavy particles. In the process, the parameters of the theory change, and new, nonrenormalizable interactions may be introduced. Thus the Lagrangian of the effective theory below M has the form

$$\mathcal{L}(\phi) + \delta\mathcal{L}(\phi), \quad (3.16)$$

H wave function renormalization $1 - \frac{1}{2} \frac{g_{\text{exp}}^2}{16\pi^2} \delta \mathcal{L}_H$

$$\begin{aligned}
