Note on the Radiation Field of the Electron

F. BLOCH AND A. NORDSIECK*

Stanford University, California

(Received May 14, 1937)

Previous methods of treating radiative corrections in non-stationary processes such as the scattering of an electron in an atomic field or the emission of a β -ray, by an expansion in powers of $e^2/\hbar c$, are defective in that they predict infinite low frequency corrections to the transition probabilities. This difficulty can be avoided by a method developed here which is based on the alternative assumption that $e^2\omega/mc^2$, $\hbar\omega/mc^2$ and $\hbar\omega/c\Delta p$ (ω =angular frequency of radiation, Δp =change in momentum of electron) are small compared to unity. In contrast to the expansion in powers of $e^2/\hbar c$, this permits the transition to the classical limit $\hbar=0$.

External perturbations on the electron are treated in the Born approximation. It is shown that for frequencies such that the above three parameters are negligible the quantum mechanical calculation yields just the directly reinterpreted results of the classical formulae, namely that the total probability of a given change in the motion of the electron is unaffected by the interaction with radiation, and that the mean number of emitted quanta is infinite in such a way that the mean radiated energy is equal to the energy radiated classically in the corresponding trajectory.

A remarkable achievement, before quantum field theory was born.

Practice

Just a **formal issue** in quantum field theory? Are there **practical applications**?

- ▶ Higher order calculations at colliders cross **hinge** upon **cancellation** of divergences between **virtual corrections** and **real emission** contributions.
 - ▶ **Cancellation** must be performed **analytically** before numerical integrations.
 - ▶ Need **local counterterms** for matrix elements in **all singular regions**.
 - ▶ State of the art: **NLO** multileg. **NNLO** available only for e^+e^- annihilation.
- ▶ **Cancellations** leave behind **large logarithms**: they must be **resummed**.

$$\underbrace{\frac{1}{\epsilon}}_{\text{virtual}} + \underbrace{(Q^2)^\epsilon \int_0^{m^2} \frac{dk^2}{(k^2)^{1+\epsilon}}}_{\text{real}} \implies \ln(m^2/Q^2),$$

- ▶ For **inclusive observables**: analytic resummation to high logarithmic accuracy.
- ▶ For **exclusive final states**: parton shower event generators, **(N)LL** accuracy.
- ▶ **Resummation** probes the **all-order** structure of perturbation theory.
 - ▶ **Power-suppressed corrections** to QCD cross sections can be studied
 - ▶ Links to the **strong coupling regime** can be established for **SUSY** gauge theories.

Modern History

Factorization

$$\mathcal{M}_{\{r_i\}} \left(\frac{p_i}{\mu}, \alpha_s(\mu^2), \epsilon \right) = \sum_L \mathcal{M}_L \left(\frac{p_i}{\mu}, \alpha_s(\mu^2), \epsilon \right) (c_L)_{\{r_i\}}$$

$$\begin{aligned} \mathcal{M}_L \left(\frac{p_i}{\mu}, \alpha_s(\mu^2), \epsilon \right) &= \bar{S}_{LK} \left(\rho_{ij}, \alpha_s(\mu^2), \epsilon \right) H_K \left(\frac{2p_i \cdot p_j}{\mu^2}, \frac{(2p_i \cdot n_i)^2}{n_i^2 \mu^2}, \alpha_s(\mu^2), \epsilon \right) \\ &\quad \times \prod_{i=1}^n J_i \left(\frac{(2p_i \cdot n_i)^2}{n_i^2 \mu^2}, \alpha_s(\mu^2), \epsilon \right) \end{aligned}$$

Progress

- ▶ Exponentiation applies to **non-abelian** gauge theories.
- ▶ Exponentiation extends to **collinear** divergences.
- ▶ Exponentiation is performed at the **amplitude** level.
- ▶ An optimal **regularization scheme** is used.

At Tevatron

Z boson spectrum at Tevatron (A. Kulesza *et al.*, hep-ph/0207148)

CDF data on Z production compared with QCD predictions at fixed order (dotted), with resummation (dashed), and with the inclusion of power corrections (solid).

Higgs boson spectrum at LHC (M. Grazzini, hep-ph/0512025)

Predictions for the q_T spectrum of Higgs bosons produced via gluon fusion at the LHC, with and without resummation.

For theory

- ▶ Understanding **long-distance singularities** to all orders provides a **window** into **non-perturbative** effects.
- ▶ The structure of **long-distance singularities** is **universal** for all **massless gauge theories**.
- ▶ A **very special theory** has emerged as a **theoretical laboratory**:
 $\mathcal{N} = 4$ Super Yang-Mills.
 - ▶ It is conformal invariant: $\beta_{\mathcal{N}=4}(\alpha_s) = 0$.
 - ▶ Exponentiation of **IR/C** poles in scattering amplitudes **simplifies**.
 - ▶ AdS/CFT suggests a ‘simple’ description **at strong coupling**, in the **planar limit**.
 - ▶ Exponentiation has been observed for **MHV** amplitudes up to **five legs**.
 - ▶ Higher-point amplitudes are **strongly constrained** by (super)conformal symmetry.
 - ▶ A **string calculation** at **strong coupling** matches the **perturbative result**.
 - ▶ Amplitudes admit a **dual description** in terms of **polygonal Wilson loops**.
 - ▶ Integrability leads to possibly **exact expressions** for **anomalous dimensions**.

Tools: dimensional regularization

Nonabelian exponentiation of **IR/C** poles requires **d -dimensional** evolution equations. The **running coupling** in $d = 4 - 2\epsilon$ obeys

$$\mu \frac{\partial \bar{\alpha}}{\partial \mu} \equiv \beta(\epsilon, \bar{\alpha}) = -2\epsilon \bar{\alpha} + \hat{\beta}(\bar{\alpha}) \quad , \quad \hat{\beta}(\bar{\alpha}) = -\frac{\bar{\alpha}^2}{2\pi} \sum_{n=0}^{\infty} b_n \left(\frac{\bar{\alpha}}{\pi}\right)^n .$$

The **one-loop** solution is

$$\bar{\alpha}(\mu^2, \epsilon) = \alpha_s(\mu_0^2) \left[\left(\frac{\mu^2}{\mu_0^2}\right)^\epsilon - \frac{1}{\epsilon} \left(1 - \left(\frac{\mu^2}{\mu_0^2}\right)^\epsilon\right) \frac{b_0}{4\pi} \alpha_s(\mu_0^2) \right]^{-1} .$$

The β function develops an **IR free** fixed point, so that $\bar{\alpha}(0, \epsilon) = 0$ for $\epsilon < 0$. The **Landau pole** is at

$$\mu^2 = \Lambda^2 \equiv Q^2 \left(1 + \frac{4\pi\epsilon}{b_0\alpha_s(Q^2)}\right)^{-1/\epsilon} .$$

- ▶ Integrations over the **scale of the coupling** can be **analytically** performed.
- ▶ All infrared and collinear poles arise **by integration** of $\alpha_s(\mu^2, \epsilon)$.

Tools: factorization

All factorizations separating dynamics at different energy scales lead to resummation of logarithms of the ratio of scales.

- ▶ Renormalization group logarithms.

Renormalization factorizes cutoff dependence

$$G_0^{(n)}(p_i, \Lambda, g_0) = \prod_{i=1}^n Z_i^{1/2}(\Lambda/\mu, g(\mu)) G_R^{(n)}(p_i, \mu, g(\mu)) ,$$

$$\frac{dG_0^{(n)}}{d\mu} = 0 \quad \rightarrow \quad \frac{d \log G_R^{(n)}}{d \log \mu} = - \sum_{i=1}^n \gamma_i(g(\mu)) .$$

- ▶ RG evolution resums $\alpha_s^n(\mu^2) \log^n(Q^2/\mu^2)$ into $\alpha_s(Q^2)$.

Note: Factorization is the difficult step. It requires a diagrammatic analysis

- ▶ all-order power counting (UV, IR, collinear ...);
- ▶ implementation of gauge invariance via Ward identities.

Tools: factorization

- ▶ Collinear factorization logarithms.

Mellin moments of partonic DIS structure functions factorize

$$\tilde{F}_2 \left(N, \frac{Q^2}{m^2}, \alpha_s \right) = \tilde{C} \left(N, \frac{Q^2}{\mu_F^2}, \alpha_s \right) \tilde{f} \left(N, \frac{\mu_F^2}{m^2}, \alpha_s \right)$$

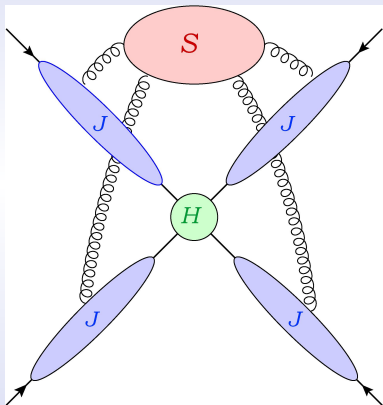

$$\frac{d\tilde{F}_2}{d\mu_F} = 0 \quad \rightarrow \quad \frac{d \log \tilde{f}}{d \log \mu_F} = \gamma_N(\alpha_s) .$$

- ▶ Altarelli-Parisi evolution resums collinear logarithms into evolved parton distributions (or fragmentation functions).

Note: Sudakov (double) logarithms are more difficult.

- ▶ A double factorization is required: hard vs. collinear vs. soft. Gauge invariance plays a key role in the decoupling.
- ▶ After identification of the relevant modes, effective field theory can be used (SCET).

Sudakov factorization

Leading regions for Sudakov factorization.

- ▶ Divergences arise in **fixed-angle** amplitudes from **leading regions** in loop momentum space.
- ▶ Soft gluons factorize both from **hard (easy)** and from **collinear (intricate)** virtual exchanges.
- ▶ Jet functions J represent **color singlet** evolution of external hard partons.
- ▶ The soft function S is a **matrix** mixing the available **color representations**.
- ▶ In the **planar limit** soft exchanges are **confined** to wedges: $S \propto \mathbf{I}$.
- ▶ In the **planar limit** S can be reabsorbed defining jets J as square roots of elementary form factors.
- ▶ Beyond the planar limit S is determined by an anomalous dimension matrix Γ_S .
- ▶ Phenomenological applications to jet and heavy quark production at hadron colliders.

Form Factors and Planar Amplitudes

(with Lance Dixon and George Sterman)

Gauge theory form factors

Consider as an example the **quark form factor**

$$\Gamma_{\mu}(p_1, p_2; \mu^2, \epsilon) \equiv \langle 0 | J_{\mu}(0) | p_1, p_2 \rangle = \bar{v}(p_2) \gamma_{\mu} u(p_1) \Gamma \left(\frac{Q^2}{\mu^2}, \alpha_s(\mu^2), \epsilon \right) .$$

- ▶ The form factor obeys the **evolution equation**

$$Q^2 \frac{\partial}{\partial Q^2} \log \left[\Gamma \left(\frac{Q^2}{\mu^2}, \alpha_s(\mu^2), \epsilon \right) \right] = \frac{1}{2} \left[K \left(\epsilon, \alpha_s(\mu^2) \right) + G \left(\frac{Q^2}{\mu^2}, \alpha_s(\mu^2), \epsilon \right) \right] ,$$

- ▶ **Renormalization group invariance** requires

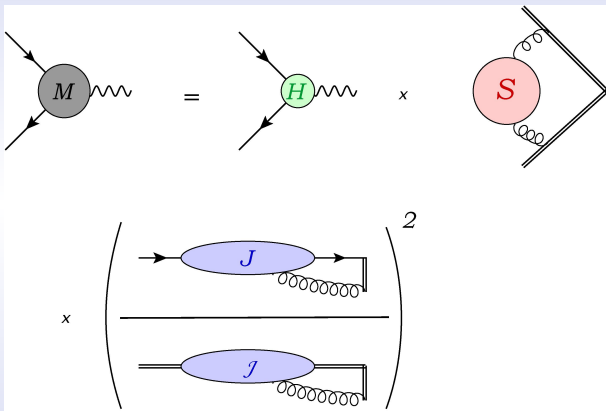

$$\mu \frac{dG}{d\mu} = -\mu \frac{dK}{d\mu} = \gamma_K \left(\alpha_s(\mu^2) \right) .$$

$\gamma_K(\alpha_s)$ is the **cusplike anomalous dimension** (G. Korchemsky and A. Radyushkin; ...).

- ▶ **Dimensional regularization** provides a **trivial initial condition** for evolution if $\epsilon < 0$ (for **IR** regularization).

$$\bar{\alpha}(\mu^2 = 0, \epsilon < 0) = 0 \rightarrow \Gamma \left(0, \alpha_s(\mu^2), \epsilon \right) = \Gamma \left(1, \bar{\alpha}(0, \epsilon), \epsilon \right) = 1 .$$

Detailed factorization

Operator factorization for the Sudakov form factor, with subtractions.

Operator definitions

The **functional form** of this graphical factorization is

$$\Gamma\left(\frac{Q^2}{\mu^2}, \alpha_s(\mu^2), \epsilon\right) = H\left(\frac{Q^2}{\mu^2}, \frac{(p_i \cdot n_i)^2}{n_i^2 \mu^2}, \alpha_s(\mu^2), \epsilon\right) \times \mathcal{S}\left(\beta_1 \cdot \beta_2, \alpha_s(\mu^2), \epsilon\right) \\ \times \prod_{i=1}^2 \left[\frac{J\left(\frac{(p_i \cdot n_i)^2}{n_i^2 \mu^2}, \alpha_s(\mu^2), \epsilon\right)}{\mathcal{J}\left(\frac{(\beta_i \cdot n_i)^2}{n_i^2}, \alpha_s(\mu^2), \epsilon\right)} \right].$$

We introduced **factorization vectors** n_i^μ , with $n_i^2 \neq 0$, to define the **jets**,

$$J\left(\frac{(p \cdot n)^2}{n^2 \mu^2}, \alpha_s(\mu^2), \epsilon\right) u(p) = \langle 0 | \Phi_n(\infty, 0) \psi(0) | p \rangle.$$

where Φ_n is the **Wilson line** operator along the direction n^μ .

$$\Phi_n(\lambda_2, \lambda_1) = P \exp \left[ig \int_{\lambda_1}^{\lambda_2} d\lambda n \cdot A(\lambda n) \right].$$

The jet J has **collinear** divergences only along p .

Operator definitions

The soft function \mathcal{S} is the eikonal limit of the massless form factor

$$\mathcal{S}(\beta_1 \cdot \beta_2, \alpha_s(\mu^2), \epsilon) = \langle 0 | \Phi_{\beta_2}(\infty, 0) \Phi_{\beta_1}(0, -\infty) | 0 \rangle .$$

Soft-collinear regions are subtracted dividing by eikonal jets \mathcal{J} .

$$\mathcal{J}\left(\frac{(\beta_1 \cdot n_1)^2}{n_1^2}, \alpha_s(\mu^2), \epsilon\right) = \langle 0 | \Phi_{n_1}(\infty, 0) \Phi_{\beta_1}(0, -\infty) | 0 \rangle ,$$

- ▶ \mathcal{S} and \mathcal{J} are pure counterterms in dimensional regularization.
- ▶ β_i -dependence of \mathcal{S} and \mathcal{J} violates rescaling invariance of Wilson lines.
⇒ It arises from double poles, associated with γ_K .
- ▶ A single pole function where the cusp anomaly cancels is

$$\bar{\mathcal{S}}(\rho_{12}, \alpha_s(\mu^2), \epsilon) \equiv \frac{\mathcal{S}(\beta_1 \cdot \beta_2, \alpha_s(\mu^2), \epsilon)}{\prod_{i=1}^2 \mathcal{J}\left(\frac{(\beta_i \cdot n_i)^2}{n_i^2}, \alpha_s(\mu^2), \epsilon\right)}$$

It can only depend on the scaling variable

$$\rho_{12} \equiv \frac{(\beta_1 \cdot \beta_2)^2 n_1^2 n_2^2}{(\beta_1 \cdot n_1)^2 (\beta_2 \cdot n_2)^2} .$$

Jet evolution

The full form factor does not depend on the factorization vectors n_i^μ .

Defining $x_i \equiv (\beta_i \cdot n_i)^2 / n_i^2$,

$$x_i \frac{\partial}{\partial x_i} \log \Gamma \left(\frac{Q^2}{\mu^2}, \alpha_s(\mu^2), \epsilon \right) = 0.$$

This dictates the evolution of the jet J , through a ‘ $K + G$ ’ equation

$$\begin{aligned} x_i \frac{\partial}{\partial x_i} \log J_i &= - x_i \frac{\partial}{\partial x_i} \log H + x_i \frac{\partial}{\partial x_i} \log \mathcal{J}_i \\ &\equiv \frac{1}{2} \left[\mathcal{G}_i(x_i, \alpha_s(\mu^2), \epsilon) + \mathcal{K}(\alpha_s(\mu^2), \epsilon) \right], \end{aligned}$$

Imposing RG invariance of the form factor

$$\gamma_{\overline{S}}(\rho_{12}, \alpha_s) + \gamma_H(\rho_{12}, \alpha_s) + 2\gamma_J(\alpha_s) = 0.$$

leads to the final evolution equation

$$Q \frac{\partial}{\partial Q} \log \Gamma = \beta(\epsilon, \alpha_s) \frac{\partial}{\partial \alpha_s} \log H - \gamma_{\overline{S}} - 2\gamma_J + \sum_{i=1}^2 (\mathcal{G}_i + \mathcal{K}).$$

Results for Sudakov form factors

- ▶ The counterterm function K is determined by γ_K .

$$\mu \frac{d}{d\mu} K(\epsilon, \alpha_s) = -\gamma_K(\alpha_s) \implies K(\epsilon, \alpha_s(\mu^2)) = -\frac{1}{2} \int_0^{\mu^2} \frac{d\lambda^2}{\lambda^2} \gamma_K(\bar{\alpha}(\lambda^2, \epsilon)).$$

- ▶ The form factor can be written in terms of just G and γ_K ,

$$\Gamma(Q^2, \epsilon) = \exp \left\{ \frac{1}{2} \int_0^{-Q^2} \frac{d\xi^2}{\xi^2} \left[G(-1, \bar{\alpha}(\xi^2, \epsilon), \epsilon) - \frac{1}{2} \gamma_K(\bar{\alpha}(\xi^2, \epsilon)) \log\left(\frac{-Q^2}{\xi^2}\right) \right] \right\}.$$

\implies In general, poles up to $\alpha_s^n/\epsilon^{n+1}$ appear in the exponent.

- ▶ The ratio of the timelike to the spacelike form factor is

$$\log \left[\frac{\Gamma(Q^2, \epsilon)}{\Gamma(-Q^2, \epsilon)} \right] = i\frac{\pi}{2} K(\epsilon) + \frac{i}{2} \int_0^\pi \left[G(\bar{\alpha}(e^{i\theta} Q^2), \epsilon) - \frac{i}{2} \int_0^\theta d\phi \gamma_K(\bar{\alpha}(e^{i\phi} Q^2)) \right]$$

\implies Infinities are confined to a phase given by γ_K .

\implies The modulus of the ratio is finite, and physically relevant.

Form factors in $\mathcal{N} = 4$ SYM

- ▶ In $d = 4 - 2\epsilon$ conformal invariance is broken and $\beta(\alpha_s) = -2\epsilon\alpha_s$.
- ▶ All integrations are trivial. The exponent has only double and single poles to all orders (Z. Bern, L. Dixon, A. Smirnov).

$$\begin{aligned}\log \left[\Gamma \left(\frac{Q^2}{\mu^2}, \alpha_s(\mu^2), \epsilon \right) \right] &= -\frac{1}{2} \sum_{n=1}^{\infty} \left(\frac{\alpha_s(\mu^2)}{\pi} \right)^n \left(\frac{\mu^2}{-Q^2} \right)^{n\epsilon} \left[\frac{\gamma_K^{(n)}}{2n^2\epsilon^2} + \frac{G^{(n)}(\epsilon)}{n\epsilon} \right] \\ &= -\frac{1}{2} \sum_{n=1}^{\infty} \left(\frac{\alpha_s(Q^2)}{\pi} \right)^n e^{-i\pi n\epsilon} \left[\frac{\gamma_K^{(n)}}{2n^2\epsilon^2} + \frac{G^{(n)}(\epsilon)}{n\epsilon} \right],\end{aligned}$$

- ▶ In the planar limit this captures all singularities of fixed-angle amplitudes in $\mathcal{N} = 4$ SYM. The structure remains valid at strong coupling, in the planar limit (F. Alday, J. Maldacena).
- ▶ The analytic continuation yields a finite result in four dimensions, arguably exact.

$$\left| \frac{\Gamma(Q^2)}{\Gamma(-Q^2)} \right|^2 = \exp \left[\frac{\pi^2}{4} \gamma_K(\alpha_s(Q^2)) \right].$$

Characterizing $G(\alpha_s, \epsilon)$

The **single-pole function** $G(\alpha_s, \epsilon)$ is a sum of anomalous dimensions

$$G(\alpha_s, \epsilon) = \beta(\epsilon, \alpha_s) \frac{\partial}{\partial \alpha_s} \log H - \gamma_{\bar{S}} - 2\gamma_J + \sum_{i=1}^2 G_i,$$

In $d = 4 - 2\epsilon$ **finite remainders** can be neatly exponentiated

$$C(\alpha_s(Q^2), \epsilon) = \exp \left[\int_0^{Q^2} \frac{d\xi^2}{\xi^2} \left\{ \frac{d \log C(\bar{\alpha}(\xi^2, \epsilon), \epsilon)}{d \ln \xi^2} \right\} \right] \equiv \exp \left[\frac{1}{2} \int_0^{Q^2} \frac{d\xi^2}{\xi^2} G_C(\bar{\alpha}(\xi^2, \epsilon), \epsilon) \right]$$

The **soft function** exponentiates **like** the full form factor

$$S(\alpha_s(\mu^2), \epsilon) = \exp \left\{ \frac{1}{2} \int_0^{\mu^2} \frac{d\xi^2}{\xi^2} \left[G_{\text{eik}}(\bar{\alpha}(\xi^2, \epsilon)) - \frac{1}{2} \gamma_K(\bar{\alpha}(\xi^2, \epsilon)) \log \left(\frac{\mu^2}{\xi^2} \right) \right] \right\}.$$

$G(\alpha_s, \epsilon)$ is then simply related to **collinear splitting functions** and to the **eikonal approximation**

$$G(\alpha_s, \epsilon) = 2B_{\bar{S}}(\alpha_s) + G_{\text{eik}}(\alpha_s) + G_{\bar{H}}(\alpha_s, \epsilon),$$

$\Rightarrow G_{\bar{H}}$ does **not** generate poles; it **vanishes** in $\mathcal{N} = 4$ SYM.

\Rightarrow Checked at **strong coupling**, in the **planar limit** (F. Alday).

Beyond the Planar Limit

(with Einan Gardi)

Soft anomalous dimensions

The soft function \mathcal{S} obeys a matrix RG evolution equation

$$\mu \frac{d}{d\mu} \mathcal{S}_{IK}(\beta_i \cdot \beta_j, \alpha_s(\mu^2), \epsilon) = -\Gamma_{IJ}^{\mathcal{S}}(\beta_i \cdot \beta_j, \alpha_s(\mu^2), \epsilon) \mathcal{S}_{JK}(\beta_i \cdot \beta_j, \alpha_s(\mu^2), \epsilon),$$

- **Note:** $\Gamma^{\mathcal{S}}$ is singular due to overlapping UV and collinear poles.

As before, \mathcal{S} is a pure counterterm. In dimensional regularization, then

$$\mathcal{S}(\beta_i \cdot \beta_j, \alpha_s(\mu^2), \epsilon) = P \exp \left[-\frac{1}{2} \int_0^{\mu^2} \frac{d\xi^2}{\xi^2} \Gamma^{\mathcal{S}}(\beta_i \cdot \beta_j, \alpha_s(\xi^2), \epsilon), \epsilon \right].$$

Double poles cancel in the reduced soft function

$$\bar{\mathcal{S}}_{LK}(\rho_{ij}, \alpha_s(\mu^2), \epsilon) = \frac{\mathcal{S}_{LK}(\beta_i \cdot \beta_j, \alpha_s(\mu^2), \epsilon)}{\prod_{i=1}^n \mathcal{J}_i \left(\frac{(\beta_i \cdot n_i)^2}{n_i^2}, \alpha_s(\mu^2), \epsilon \right)}$$

- $\bar{\mathcal{S}}$ must depend on rescaling invariant variables, $\rho_{ij} \equiv \frac{n_i^2 n_j^2 (\beta_i \cdot \beta_j)^2}{(\beta_i \cdot n_i)^2 (\beta_j \cdot n_j)^2}$.
- The anomalous dimension $\Gamma^{\bar{\mathcal{S}}}(\rho_{ij}, \alpha_s)$ for the evolution of $\bar{\mathcal{S}}$ is finite.

Surprising simplicity

- ▶ $\Gamma^{\mathcal{S}}$ can be computed from UV poles of \mathcal{S}
- ▶ Non-abelian eikonal exponentiation selects the relevant diagrams: webs
- ▶ $\Gamma^{\mathcal{S}}$ appears highly complex at high orders.

A web contributing to $\Gamma^{\mathcal{S}}$.

The two-loop calculation (M. Aybat, L. Dixon, G. Sterman) leads to a surprising result: for any number of light-like eikonal lines

$$\Gamma_S^{(2)} = \frac{\kappa}{2} \Gamma_S^{(1)} \quad \kappa = \left(\frac{67}{18} - \zeta(2) \right) C_A - \frac{10}{9} T_F C_F.$$

- ▶ No new kinematic dependence; no new matrix structure.
- ▶ κ is the two-loop coefficient of γ_K , rescaled by the appropriate Casimir,

$$\gamma_K^{(i)}(\alpha_s) = C^{(i)} \left[2 \frac{\alpha_s}{\pi} + \kappa \left(\frac{\alpha_s}{\pi} \right)^2 \right] + \mathcal{O}(\alpha_s^3).$$

Factorization constraints

- ▶ The classical **rescaling symmetry** of Wilson line correlators under $\beta_i \rightarrow \kappa \beta_i$ is **violated** only through the **cuspl anomaly**.
⇒ For **eikonal jets**, no β_i dependence is possible at all **except** through the cusp.
- ▶ In the **reduced** soft function $\bar{\mathcal{S}}$ the cusp anomaly **cancels**.
⇒ $\bar{\mathcal{S}}$ must depend on β_i **only** through **rescaling-invariant** combinations such as ρ_{ij} , or, for $n \geq 4$ legs, the **cross ratios** $\rho_{ijkl} \equiv (\beta_i \cdot \beta_j)(\beta_k \cdot \beta_l) / (\beta_i \cdot \beta_k)(\beta_j \cdot \beta_l)$

Consider then the anomalous dimension for the **reduced** soft function

$$\Gamma_{IJ}^{\bar{\mathcal{S}}}(\rho_{ij}, \alpha_s(\mu^2)) = \Gamma_{IJ}^{\mathcal{S}}(\beta_i \cdot \beta_j, \alpha_s(\mu^2), \epsilon) - \delta_{IJ} \sum_{k=1}^n \gamma_{\mathcal{J}_k} \left(\frac{(\beta_k \cdot n_k)^2}{n_k^2}, \alpha_s(\mu^2), \epsilon \right).$$

This poses **strong constraints** on the **soft matrix**. Indeed

- ▶ Singular terms in $\Gamma^{\mathcal{S}}$ must be **diagonal** and **proportional** to γ_K .
- ▶ Finite diagonal terms must **conspire** to construct ρ_{ij} 's combining $\beta_i \cdot \beta_j$ with x_i .
- ▶ Off-diagonal terms in $\Gamma^{\mathcal{S}}$ must be **finite**, and must depend **only** on the cross-ratios ρ_{ijkl} .

Factorization constraints

The **constraints** can be formalized simply by using the **chain rule**.

$\Gamma^{\bar{S}}$ depends on x_i in a **simple** way.

$$x_i \frac{\partial}{\partial x_i} \Gamma_{IJ}^{\bar{S}}(\rho_{ij}, \alpha_s) = -\delta_{IJ} x_i \frac{\partial}{\partial x_i} \gamma_{\mathcal{J}}(x_i, \alpha_s, \epsilon) = -\frac{1}{4} \gamma_K^{(i)}(\alpha_s) \delta_{IJ}.$$

This leads to a **linear equation** for the dependence of $\Gamma^{\bar{S}}$ on ρ_{ij}

$$\sum_{j \neq i} \frac{\partial}{\partial \ln(\rho_{ij})} \Gamma_{MN}^{\bar{S}}(\rho_{ij}, \alpha_s) = \frac{1}{4} \gamma_K^{(i)}(\alpha_s) \delta_{MN} \quad \forall i,$$

- ▶ The equation relates $\Gamma^{\bar{S}}$ to γ_K to all orders in perturbation theory
⇒ and should remain true at strong coupling as well.
- ▶ It correlates **color** and **kinematics** for any number of hard partons.
- ▶ It admits a **unique solution** for amplitudes with up to three hard partons.
⇒ For $n \geq 4$ hard partons, functions of ρ_{ijkl} solve the **homogeneous equation**.

The dipole formula

The cusp anomalous dimension exhibits Casimir scaling up to three loops.

- ▶ $\gamma_K^{(i)}(\alpha_s) = C_i \hat{\gamma}_K(\alpha_s)$ with C_i the quadratic Casimir and $\hat{\gamma}_K(\alpha_s)$ universal.

Denoting with $\tilde{\gamma}_K^{(i)}$ possible terms violating Casimir scaling, we write

$$\sum_{j \neq i} \frac{\partial}{\partial \ln(\rho_{ij})} \Gamma^{\bar{S}}(\rho_{ij}, \alpha_s) = \frac{1}{4} \left[C_i \hat{\gamma}_K(\alpha_s) + \tilde{\gamma}_K^{(i)}(\alpha_s) \right] \quad \forall i,$$

By linearity, using the color generator notation, the scaling term yields

$$\sum_{j \neq i} \frac{\partial}{\partial \ln(\rho_{ij})} \Gamma_{\text{Q.C.}}^{\bar{S}}(\rho_{ij}, \alpha_s) = \frac{1}{4} T_i \cdot T_i \hat{\gamma}_K(\alpha_s), \quad \forall i$$

An all-order solution is the dipole formula (E. Gardi, LM; T. Becher, M. Neubert)

$$\Gamma_{\text{dip}}^{\bar{S}}(\rho_{ij}, \alpha_s) = -\frac{1}{8} \hat{\gamma}_K(\alpha_s) \sum_{j \neq i} \ln(\rho_{ij}) T_i \cdot T_j + \frac{1}{2} \hat{\delta}_{\bar{S}}(\alpha_s) \sum_i T_i \cdot T_i,$$

as easily checked using color conservation, $\sum_i T_i = 0$.

Note: all known results for massless gauge theories are of this form.

The full amplitude

It is possible to construct a **dipole formula** for the **full amplitude** enforcing the **cancellation** of the dependence on the **factorization vectors** n_i through

$$\ln \left(\frac{(2p_i \cdot n_i)^2}{n_i^2} \right) + \ln \left(\frac{(2p_j \cdot n_j)^2}{n_j^2} \right) + \ln \left(\frac{(-\beta_i \cdot \beta_j)^2 n_i^2 n_j^2}{2(\beta_i \cdot n_i)^2 2(\beta_j \cdot n_j)^2} \right) = 2 \ln (-2p_i \cdot p_j) .$$

Soft and **collinear** singularities can then be **collected** in a **matrix** Z

$$\mathcal{M} \left(\frac{p_i}{\mu}, \alpha_s(\mu^2), \epsilon \right) = Z \left(\frac{p_i}{\mu_f}, \alpha_s(\mu_f^2), \epsilon \right) \mathcal{H} \left(\frac{p_i}{\mu}, \frac{\mu_f}{\mu}, \alpha_s(\mu^2), \epsilon \right) ,$$

satisfying a **matrix** evolution equation

$$\frac{d}{d \ln \mu_f} Z \left(\frac{p_i}{\mu_f}, \alpha_s(\mu_f^2), \epsilon \right) = -\Gamma \left(\frac{p_i}{\mu_f}, \alpha_s(\mu_f^2) \right) Z \left(\frac{p_i}{\mu_f}, \alpha_s(\mu_f^2), \epsilon \right) .$$

The **dipole structure** of $\Gamma^{\overline{S}}$ is **inherited** by Γ , which reads (T. Becher, M. Neubert)

$$\Gamma_{\text{dip}} \left(\frac{p_i}{\lambda}, \alpha_s(\lambda^2) \right) = -\frac{1}{4} \widehat{\gamma}_K \left(\alpha_s(\lambda^2) \right) \sum_{j \neq i} \ln \left(\frac{-2 p_i \cdot p_j}{\lambda^2} \right) \mathbf{T}_i \cdot \mathbf{T}_j + \sum_{i=1}^n \gamma_{J_i} \left(\alpha_s(\lambda^2) \right) .$$

Beyond the dipole formula

(with Lance Dixon and Einan Gardi)

Beyond the minimal solution

- ▶ The cusp anomalous dimension may violate Casimir scaling starting at four loops. This would add a contribution $\Gamma_{\text{H.C.}}^{\bar{S}}$ satisfying

$$\sum_{j, j \neq i} \frac{\partial}{\partial \ln(\rho_{ij})} \Gamma_{\text{H.C.}}^{\bar{S}}(\rho_{ij}, \alpha_s) = \frac{1}{4} \tilde{\gamma}_K^{(i)}(\alpha_s), \quad \forall i.$$

- ▶ For $n \geq 4$ the constraints do not uniquely determine $\Gamma^{\bar{S}}$: one may write

$$\Gamma^{\bar{S}}(\rho_{ij}, \alpha_s) = \Gamma_{\text{dip}}^{\bar{S}}(\rho_{ij}, \alpha_s) + \Delta^{\bar{S}}(\rho_{ij}, \alpha_s),$$

where $\Delta^{\bar{S}}$ solves the homogeneous equation

$$\sum_{j \neq i} \frac{\partial}{\partial \ln(\rho_{ij})} \Delta^{\bar{S}}(\rho_{ij}, \alpha_s) = 0 \quad \Leftrightarrow \quad \Delta^{\bar{S}} = \Delta^{\bar{S}}(\rho_{ijkl}, \alpha_s).$$

- ▶ By eikonal exponentiation $\Delta^{\bar{S}}$ must directly correlate four partons.
 - ▶ A nontrivial function of ρ_{ijkl} cannot appear in $\Gamma^{\bar{S}}$ at two loops.

$$\bar{\mathbf{H}}_{[l]} = \sum_{j,k,l} \sum_{a,b,c} i f_{abc} T_j^a T_k^b T_l^c \ln(\rho_{ijkl}) \ln(\rho_{iklj}) \ln(\rho_{iljk}).$$

- ▶ The minimal solution holds for ‘matter loop’ diagrams at three loops (L. Dixon).

Collinear constraints

Factorization of **fixed-angle** amplitudes **breaks down** in **collinear** limits, as $p_i \cdot p_j \rightarrow 0$. New singularities are **captured** by a **universal splitting function**

$$\mathcal{M}_n(p_1, p_2, p_j; \mu, \epsilon) \xrightarrow{1||2} \mathbf{Sp}(p_1, p_2; \mu, \epsilon) \mathcal{M}_{n-1}(P, p_j; \mu, \epsilon) .$$

Infrared poles of the splitting function are generated by a **splitting anomalous dimension**

$$\mathbf{Sp}(p_1, p_2; \mu, \epsilon) = \mathbf{Sp}_{\mathcal{H}}^{(0)}(p_1, p_2; \mu, \epsilon) \exp \left[-\frac{1}{2} \int_0^{\mu^2} \frac{d\lambda^2}{\lambda^2} \Gamma_{\mathbf{Sp}}(p_1, p_2; \lambda) \right] ,$$

related to the **soft anomalous dimensions** of the two amplitudes:

$$\Gamma_{\mathbf{Sp}}(p_1, p_2; \mu_f) \equiv \Gamma_n(p_1, p_2, p_j; \mu_f) - \Gamma_{n-1}(P, p_j; \mu_f) .$$

If the **dipole formula** receives corrections, so does the **splitting amplitude**

$$\Gamma_{\mathbf{Sp}}(p_1, p_2; \lambda) = \Gamma_{\mathbf{Sp}, \text{dip}}(p_1, p_2; \lambda) + \Delta_n(\rho_{ijkl}; \lambda) - \Delta_{n-1}(\rho_{ijkl}; \lambda) .$$

Universality of $\Gamma_{\mathbf{Sp}}$ **constrains** $\Delta_n - \Delta_{n-1}$: it must depend **only** on the **collinear** parton pair (T. Becher, M. Neubert).

Bose symmetry, transcendentality

Contributions to $\Delta_n(\rho_{ijkl})$ arise from gluon subdiagrams of eikonal correlators. They must be Bose symmetric. With four hard partons,

$$\Delta_4(\rho_{ijkl}) = \sum_i h_{abcd}^{(i)} \mathbf{T}_i^a \mathbf{T}_j^b \mathbf{T}_k^c \mathbf{T}_l^d \Delta_{4, \text{kin}}^{(i)}(\rho_{ijkl}),$$

the symmetries of $\Delta_{4, \text{kin}}^{(i)}$ must match those of $h_{abcd}^{(i)}$. For polynomials in $L_{ijkl} \equiv \log \rho_{ijkl}$ one easily matches symmetries of available color tensors

$$\Delta_4(\rho_{ijkl}) = \mathbf{T}_1^a \mathbf{T}_2^b \mathbf{T}_3^c \mathbf{T}_4^d \left[f_{ade} f_{cb}{}^e L_{1234}^{h_1} \left(L_{1423}^{h_2} L_{1342}^{h_3} - (-1)^{h_1+h_2+h_3} L_{1342}^{h_2} L_{1423}^{h_3} \right) + \text{cycl.} \right],$$

- ▶ Transcendentality constrains the powers of the logarithms. At L loops

$$h_{\text{tot}} \equiv h_1 + h_2 + h_3 \leq \tau \leq 2L - 1$$

- ▶ For $\mathcal{N} = 4$ SYM, and for any massless gauge theory at three loops the bound is expected to be saturated.
- ▶ Collinear consistency requires $h_i \geq 1$ in any monomial.

Three loops

- ▶ Δ_n can first appear at **three loops**.
- ▶ A general Δ_n is a ‘**sum over quadrupoles**’.
- ▶ Relevant **webs** are the same in $\mathcal{N} = 4$ SYM.
- ▶ The **only available** color tensors are $f_{ade} f_{cb}^e$
- ▶ Polynomials in L_{ijkl} are **severely constrained**.
- ▶ Using **Jacobi identities** for color and $L_{1234} + L_{1423} + L_{1342} = 0$ for **kinematics**, only **one structure polynomial** in L_{ijkl} survives.

Three-loop web contributing to Γ^S .

h_1	h_2	h_3	h_{tot}	comment
1	1	1	3	vanishes identically by Jacobi identity
2	1	1	4	kinematic factor vanishes identically
1	1	2	4	allowed by symmetry, excluded by transcendentality
1	2	2	5	viable possibility
3	1	1	5	viable possibility
2	1	2	5	viable possibility
1	1	3	5	viable possibility

} all coincide

Survivors

Just **one** maximal transcendentality, Bose symmetric, collinear safe **polynomial** in the logarithms survives.

$$\Delta_4^{(122)}(\rho_{ijkl}) = \mathbf{T}_1^a \mathbf{T}_2^b \mathbf{T}_3^c \mathbf{T}_4^d \left[f_{ade} f_{cb}^e L_{1234} (L_{1423} L_{1342})^2 \right. \\ \left. + f_{cae} f_{db}^e L_{1423} (L_{1234} L_{1342})^2 + f_{bae} f_{cd}^e L_{1342} (L_{1423} L_{1234})^2 \right].$$

Allowing for **polylogarithms**, structures **mimicking** the simple symmetries of L_{ijkl} must be constructed. Two **examples** are

$$\Delta_4^{(122, Li_2)}(\rho_{ijkl}) = \mathbf{T}_1^a \mathbf{T}_2^b \mathbf{T}_3^c \mathbf{T}_4^d \left[f_{ade} f_{cb}^e L_{1234} \left(\text{Li}_2(1 - \rho_{1342}) - \text{Li}_2(1 - 1/\rho_{1342}) \right) \right. \\ \left. \times \left(\text{Li}_2(1 - \rho_{1423}) - \text{Li}_2(1 - 1/\rho_{1423}) \right) + \text{cycl.} \right].$$

$$\Delta_4^{(311, Li_3)}(\rho_{ijkl}) = \mathbf{T}_1^a \mathbf{T}_2^b \mathbf{T}_3^c \mathbf{T}_4^d \left[f_{ade} f_{cb}^e \left(\text{Li}_3(1 - \rho_{1342}) - \text{Li}_3(1 - 1/\rho_{1342}) \right) L_{1423} L_{1342} + \text{cycl.} \right].$$

Higher-order polylogarithms are **ruled out** by their **trancendentality** combined with **collinear** constraints.

Perspective

- ▶ After $\mathcal{O}(10^2)$ years, **soft** and **collinear** singularities in massless gauge theories are **still a fertile field of study**.
 - ⇒ We are **probing** the **all-order** structure of the **nonabelian exponent**.
 - ⇒ All-order results **constrain**, **test** and **help** fixed order calculations.
 - ⇒ Understanding **singularities** has **phenomenological** applications through **resummation**.
- ▶ **Factorization** theorems ⇒ **Evolution** equations ⇒ **Exponentiation**.
- ▶ **Dimensional continuation** is the **simplest** and **most elegant** regulator.
 - ⇒ Transparent **mapping** **UV** ↔ **IR** for ‘**pure counterterm**’ functions.
- ▶ **Remarkable** simplifications in $\mathcal{N} = 4$ **SYM** point to **exact results**.
- ▶ Only **three functions**, γ_K , G_{eik} and B_δ determine **all** singularities in the **planar limit**, and **possibly beyond**.
- ▶ **Factorization** and classical **rescaling invariance** severely **constrain** soft anomalous dimensions to **all orders** and for **any number** of legs.
- ▶ A simple **dipole formula** may encode **all infrared singularities** for any massless gauge theory.
- ▶ The **study** of possible **corrections** to the dipole formula is **under way**.
